Project Description

The Flatirons Meal Plan Map is a web application designed for users to easily explore and find restaurants included in the Flatirons Meal Plan. The platform combines an interactive map with personalized features to enhance the dining experience for people in the program. Users can view all the participating restaurants displayed as pins on a map. Clicking on a pin reveals important details such as the restaurant's address, website, and phone number. In addition to the map, the application includes a dashboard that highlights curated content. This includes a randomly generated restaurant recommendation, a list of the most favorited restaurants across all users, and the current weekly deal offered by the meal plan. These features help users make decisions about restaurants quickly, like choosing where to eat. The platform also allows users to create and customize profiles, save their favorite restaurants for quick access, and add friends. This creates a more personalized and engaging experience. Overall, the Flatirons Meal Plan Map serves as a center for the meal plan that simplifies dining choices while promoting exploration.

Contributions

Ryan Falender

Ryan was primarily responsible for building and styling the navigation bar using Handlebars, CSS, and Bootstrap, including dynamically rendering its content. He also developed the login and registration pages, implementing validation with regex to enforce username and password requirements while maintaining a consistent, professional design and strong user experience. Additionally, Ryan led User Acceptance Testing by defining testing procedures to ensure functionality and usability. He utilized Mocha (a JavaScript test framework for running test cases) and Chai (an assertion library for verifying expected outcomes) to validate application behavior.

Pranav Konijeti

I led the development of the core mapping and data architecture. Using Leaflet and OpenStreetMap, I implemented the interactive map with real-time GPS tracking. I added pins for each restaurant location, and then optimized the geocoding scraper to handle API rate limits, transitioning the app from sequential loading to a high-performance model where all restaurant pins render instantly. I also helped debug the scrapper script made by my other teammates.

Hayden Sandau

Hayden was responsible for the friend system, profile customization system, and basic login/logout system. At the start of the project, he worked on getting a more basic version of the login, logout, and registration pages made along with the appropriate Express routes and database entries. He then pivoted to working on a profile customization system so users can customize and change their username, profile image, and real name. Then, he implemented the friend system to allow users to send friend requests and view each other's profiles. At the end, he reworked the profile image uploading system to work with AWS so the images can be stored on the cloud and accessible to users via the open internet.

Garrett Smith

I was responsible for helping with features needed to create the map. This included getting data on the restaurants like location, phone number, and an image for each restaurant. I used cheerio and axios to scrape data from the flatiron meal plan website in order to get up to date data about the restaurants on the plan. I also created a search system to the map allowing the user to enter a name or type of restaurant and give them results as well as moving the map to view the selected restaurant. I also did debugging related to these features because implementing them into existing code proved tricky.

Marie Viita

I contributed to the development of the dashboard using Node.js, Express, Handlebars, and PostgreSQL. I implemented features like the random restaurant recommendation, weekly deal display, and the ability for users to favorite restaurants. This involved writing queries to fetch data and connecting them to the frontend dashboard interface. Finally, I also worked on displaying dynamic content on the dashboard. I ensured user-specific data, such as favorites, were displayed correctly and updated.

Test Results

During UAT, users tested core workflows using the local Docker/Node/PostgreSQL environment in Chrome. The test plan included 8 total test cases, all of which passed. The tested use cases included user registration, login/authentication, unauthorized dashboard access, and dashboard restaurant recommendations.

Use cases tested:

- Registering a new account with valid information
- Handling invalid registration inputs, including mismatched passwords and short usernames
- Logging in with valid and invalid credentials
- Preventing unauthenticated users from accessing protected pages
- Viewing a dashboard restaurant recommendation
- Refreshing the dashboard to generate a new recommendation

Results:

- Total tests executed: 8
- Passed: 8
- Failed: 0

Observations:

Users were generally able to complete the registration, login, and dashboard tasks successfully. The login and registration process was described as straightforward and accessible. However, users noticed that username and password formatting requirements were not always clear before submission. Based on this feedback, a useful improvement would be to display clearer formatting instructions or validation messages before users submit the form.

Deployment

The application is deployed and accessible through the following link:
Link to deployment

Users can access the platform by navigating to the link in a browser. No installation or set up is required. Once on the site, users can register or login to explore restaurants, view the dashboard, and interact with different features.
